Localization of dopant-induced Fermi level in ZnO with CNTs/CdS/Pt as electrode. A new method for the investigation of the dopant-induced Fermi level of ZnO is presented. The new strategy consists of a thin layer of cadmium sulfide (CdS) embedded in the tube (carbon nanotube) of carbon paste electrode which is subsequently grown on a Pt counter electrode. In this paper, the electron donor (CdS) and acceptor (ZnO) are doped by the CNTs. By electrical and optical techniques, it is shown that the Fermi level of ZnO can be shifted to the conduction band, resulting in a p-type ZnO semiconductor with a hole

concentration as high as 10^{19}cm^{-3} . The energy band diagram of the new electrode is proposed, and its application to an oxygen sensor is discussed.

Geographic Information Systems (GIS) are becoming increasingly popular in many areas, including the realm of transportation planning. Although there are many transportation applications, GIS can be used for a wide variety of planning problems. For example, GIS technology can be used to model road and highway networks, or to model the commercial, residential, and industrial locations for a specific area. More specifically, a GIS can be used to define the future infrastructure of a region, and can be used to create travel routes between geographical nodes for a

community. Many GIS software products provide user-friendly interfaces for users to define routes and other modeling elements. In particular, there are many applications for generating a user-defined route for a community. Generally, this route is computed as a combination of a start and end point, and each intermediate point can be assigned a distance from the start and end points. Although the user can select each point independently, conventional GIS techniques generally combine a given point into a line that runs between the start and end points. In this regard, there are various algorithms and methods for combining the given point with the path formed between the start and end points. In transportation planning, GIS can be used to generate a

user-defined route. For example, a GIS can be used to determine the community location of a local highway, and a software user can then manually input the desired origin and destination of the highway. In
