Technical Field Embodiments of the present disclosure relate to flash memory driving circuits, and particularly, to a flash memory driving circuit capable of avoiding programming current kickback and conserving power. 2. Description of Related Art In a conventional flash memory, a programming operation is typically performed by alternately applying a high voltage level to a selected word line and a low voltage level to a word line of a memory block, which is also referred to as the page mode. However, during the programming operation, a charge sharing effect usually occurs between the word lines of the memory block being programmed with the selected word line due to the gate capacitance of the memory cells on the selected word line, and the extra charge injected into the word line may cause the charge sharing effect to increase. This may be caused by the word lines being affected by the charges injected

from the same selected word line in a short period of time. In this situation, the word lines connected to the memory cells on the selected word line are also subjected to the programming operation, even though these memory cells are being programmed. Hence, a programming current kickback occurs and the programming time increases, and the programming accuracy of the memory cells being programmed deteriorates. ΔT due to both the usual thermal conductivity at high temperatures and the e-ph interaction related ones. The anisotropy coefficient is obtained from the functional derivative of $(\frac{\partial \alpha_{i,j}(\mathbf{s})}{\partial T}) = \mu_0 \frac{d \bar{m}_{\hat{s}}}{dT} \frac{\partial \bar{m}_{\hat{s}}}{\partial T}$. Note that $\frac{\partial \bar{m}_{\hat{s}}}{\partial T}$ is obtained as the partial derivative of $\bar{m}_{\hat{s}}$ due to the last step of the calculation, which is the standard derivative with respect to $\bar{m}_{\hat{s}}$ of the average values $\langle \dots \rangle$ (the quantities of interest here are the average values over the disordered matrix, in the diluted random case) [Ziman_book]. We can calculate the superconducting temperature and the anisotropy coefficient for a given composition using the same procedure but working out the density matrix of the superconductor ρ_{SC} instead of that of the metallic phase ρ_{SC1} (the procedure is similar, the difference is that now ρ_{SC} is calculated using ρ_{1}). Considering now the superconductor-insulator transition, the metallic phase can be described by an effective chemical potential (μ)
